So there you have it: the nuclear reaction heats the fuel, the fuel heats the water to make steam, the steam spins the turbine, the turbine turns the generator, and the generator makes electricity.

The heat produced during nuclear fission in the reactor core is used to boil water into steam, which turns the blades of a steam turbine. As the turbine blades turn, they drive generators ...

The energy from the steam causes the turbine to spin, creating kinetic energy. The turbine is connected to a generator, which turns kinetic energy from the turbine into electricity!

Wind flows over the blades creating lift (similar to the effect on airplane wings), which causes the blades to turn. The blades are connected to a drive shaft that turns an electric generator, which produces ...

Nuclear power plants generate electricity by using controlled nuclear fission chain reactions to heat water and produce steam that powers turbines. Nuclear is often labeled "clean" energy because no ...

Unlike wind or solar power, nuclear power does not depend on the weather, so it can make electricity exactly when we need it. Most nuclear plants are built to make huge amounts of ...

How does a nuclear power plant work? Inside nuclear power plants, nuclear reactors and their equipment contain and control the chain reactions, most commonly fuelled by uranium-235, to ...

To generate electricity in a nuclear power plant, atoms are split through a process known as fission. Fission occurs when the nucleus of an atom, typically a heavy element such as uranium ...

This is called a chain reaction, and the whole process creates a lot of heat. The generated heat is removed from the reactor by a circulating fluid, typically water. This heat can then be used to ...

How does nuclear wind power generate electricity

This video highlights the basic principles at work in wind turbines and illustrates how the various components work to capture and convert wind energy to electricity.
